## Statement of compliance with academic ethics and the avoidance of plagiarism

I honestly declare that this dissertation is entirely my own work and none of its part has been copied from printed or electronic sources, translated from foreign sources and reproduced from essays of other researchers or students. Wherever I have been based on ideas or other people texts I clearly declare it through the good use of references following academic ethics.

(In the case that is proved that part of the essay does not constitute an original work, but a copy of an already published essay or from another source, the student will be expelled permanently from the postgraduate program).

Name and Surname (Capital letters):

BARIS EGEMEN TOKUL

Date:10/02/2026

# INTRODUCTION

The energy industry in Europe is receiving numerous transformations as a result of a number of driving forces that are all influencing towards the greater use of electricity in the transportation and heating, tremendous growth of renewable energies, supply chain and geopolitical disturbances, stringent climate regulations and the escalating demands of the clients toward digitality that offers real-time information. Besides higher variation of renewable energy forming a demand towards more flexibility and observability in the grid, it will be more demanded to deal with peak loads formed by electrification of everything, which will require creation of demand side management. In addition to the fact that poor customer experiences are expensive compared to the level of digital natives, energy corporations will need to compete on this level (European Commission, 2025; International Energy Agency, 2023). This paper is aimed at offering the opinion of a digital transformation consultant to guide E.ON SE to gain sustainable competitive advantages in a highly regulated, capital intensive environment, namely in the field of distribution network and customer solution/retail areas, and to understand whether digitalization can deliver sustainable competitive advantages to E.ON in the area of grid can be seen as a transition bottleneck (International Energy Association, 2023). The methodology of the analysis is based on a strategy-to-skills model and it relies on academic, corporate, and EU sources (Monaco, 2024; International Energy Association, 2023).

CHAPTER ONE

# 1. Drivers of digital change in energy and implications for E.ON

## 1.1 Grid complexity, connection waits, and flexibility are becoming the limiting factors.

Digitalization is transforming Europe's grid from a passive to an active, data-intensive system. Unpredictability and controllable points are increased by prosumers, heat pumps, storage, distributed generation, renewable energy, and EV charging. According to the IEA, grids that lag behind the electrical economy are at risk of supply security issues and delays in renewable energy (IEA, 2023).

As such, E.ON views the driver of digitalization as critical since much of its business model depends upon the distribution networks it operates. Consequently, digitalization has become E.ON's operational platform for enabling:

1. Observability--providing real-time visibility into the network through the use of sensors, advanced SCADA and topology knowledge;
2. Decision Automation--enabling faster automation of outage management, prioritizing maintenance needs and determining when to connect new consumers;
3. Flexibility Enablement: rather than adding more capacity, this allows demand response and distributes energy resources to reduce peak loads.

The emphasis in E.ON's digitalization strategy is focused upon the development of smart grids using digital communication, sensing, and automation technologies consistent with the IEA's conclusion that these capabilities are necessary to enable real-time grid management (E.ON, n.d.; IEA, 2023).

## 1.2 Customer expectations shifting from commodity supply to experience + outcomes

The needs of customers to work fast, have individual solutions, and be transparent are affecting retail energy all the more. Customers would rather get a monthly payment on an intangible product than be able to see consumption in real time, have automatic notifications, be able to switch tariffs seamlessly, and have built-in offers (PV + storage + EV charging). The European Commission introduces digitalization as a consumer empowerment tool through digital tools and the infrastructure of data exchange that can be used to provide new energy services (European Commission, 2025). Even though they need platform implementation, including common data models, identity and consent management, and continuous product operating model, customer solutions offer E.ON a scalable growth opportunity. The case studies mention the transition of E.ON to international digital sales platforms and a common technology platform to computerize grid and sales processes (BCG Platinaon, 2022).

## 1.3 Economics of the energy transition: efficiency pressure and capital discipline

Financial constraints drive the digital transformation: grid expansion is costly and restricted by labor and permit shortages, which increase the connection cost and delay times and regulatory hurdles. Digitalization can also make work more efficient through minimized manual labor, asset usage, and proactive maintenance. Nevertheless, such programs are viewed as IT upgrades, which fail, the barriers are not the availability of tools but organizational, regulatory, and capability-based (Monaco, 2024).

## 1.4 Data, cyber-security, and trust as strategic constraints

The vulnerability in the operational technology and the cyber threats are the two main factors leading to digitalization of utilities. Cyber risks may evolve into reliability events in utilities since digitalization may enhance resilience besides augmenting the attack surface. Firms that have integrated the security-by-design, governance, and open ethics of data in their utility, will be preferred as the regulations keep on increasing. The cloud led, standards based strategy of E.ON helps in shifting the decentralized local IT to a centralized, controlled architecture.

## 1.5 What these drivers mean strategically for E.ON

The combination of the above competitive advantages from E.ON's view point, indicates that, advantage is going to be determined by how well you can serve as a grid-and-customer platform, versus being an energy company with a layer of IT. Therefore, this would indicate:

1. Data-as-a-product – manage your customers and networks data to ensure it has quality, lineage, access and permission;
2. The automation of all things – digitize and automate end-to-end business process (connection, outage, billing, service);
3. A barrier to entry through interoperability – allow other companies' products, partner's products and/or third party market platforms to easily and efficiently connect, and work together, as indicated by European Commission (2025) with regards to the EU's plans for data exchange; and
4. A learning organization - create ongoing, daily feedback loops (monitor-learn-adapt) into day-to-day operations, not just in an R&D or Innovation lab.

CHAPTER TWO

# 2. Competencies and culture required to succeed

## 2.1 Why energy digitisation success is determined by competencies and culture.

The capital-intensive and high-stakes industries have been hard to transform digitally because technological investment is what generates the opportunity, although does not inevitably bring about changes in accountability, collaboration, or decision-making. Instead, most organizations create so-called digital theater which is the insertion of dashboards in pre-existing processes without making the customers happier, reducing the cycle time, or reliability. The three divisions and pan-European location make E.ON susceptible to issues in digitization of the distribution grid (Monaco, 2024), though these issues are known to be a challenge to digitization of the grid. The process of transformation presupposes the presence of the technical/digital, organizational leadership skills, and the culture that will enable taking the fast decisions without jeopardizing the security or the legality.

## 2.2 Core competency stack (what E.ON must build)

**1.Data and analytics capability (utility-grade):**

1. Data engineering, master data management, and governance for both OT (grid) and IT (customer) domains.
2. Advanced analytics: Load Forecasting, Asset Health Prediction, Connection Planning Optimization and Segmentation for Customer Solutions.

The IEA's Digitalisation Workstream highlights how digital technologies and data can be used to enable greater levels of integration of Variable Renewables and improve the overall reliability of the Grid. This is a direct alignment with E.ON's Network Value Proposition (IEA, n.d.).

**Cloud and platform engineering (secure, standardised, scalable):**

The E.ON strategy digitalization will specifically be pegged on standards and a clear-cut cloud plan (E.ON, 2024).The knowledge of cloud architecture, identity and access management, API administration, and observability will be required, not to mention the self-control to stream across markets and consider local regulatory constraints.

**Cybersecurity for critical infrastructure:**

The competence must not be limited to only traditional IT security but OT security, incident response and risk based governance. Competitive differentiation is a developed standard security posture in the context of energy because reliability, reputation and regulatory confidence are guaranteed.

**User-centred service design and product management:**

E.ON should have product managers that can transform technological and legal constraints into a straightforward promise such as save money, reduce emissions, avoid outages, and connect faster to make digitization generate customer value. The focus on digital selling platforms of the case of BCG indicates a transition to platform thinking and redesign the customer journey along with internal automation (BCG Platinion, 2022).

**Lean + digital process excellence:**

The automation is possible when the processes are made stable and redesigned. Process mining, Lean, and intelligent automation are some of the skills that can be used to prevent the replication of inefficiencies at a greater rate.

2.3 Cultural attributes E.ON must have (and what that would resemble in reality)

## 2.3 Cultural attributes E.ON must have (and what that would resemble in reality)

**A. "Safety and speed" as a single principle (not a trade-off):**

Risk aversion is the priority of the energy firms, whereas speed is the priority of the digital organizations. E.ON needs to integrate both of them: fast testing in low-risk settings (analytics sandboxes, digital channels) and strict change management in crucial OT fields.

**B. The learning culture that has quantifiable feedback loops:**

Making digital changes is a continuous journey; E.ON has to incentivize their teams to produce high-quality and prompt changes to the business and not just to prevent errors. To do that, they should have operational measures of change outcomes, including: Connection lead time, Outage restoration time, Customer effort score, Digital self service adoption, Cost-to-serve.

**C. Cross-functional teaming as normal operation model:**

The Silos between it, operations, customer service, etc., and that is why E.ON will need to have shared ownership of product development teams comprising grid engineers, data specialists, cybersecurity specialists, compliance specialists, and customer operations specialists. Devoid of that, Digital initiatives tend to be technically beautiful but operationally unfeasible, or, are technically unfeasible but operationally beautiful.

**D. Governance that enables, not suffocates:**

Governance in regulated businesses is inevitable. Governance is also special since it enables teams to operate expeditiously within constraints as it offers them reusable design (such data models, procurement designs, and security designs) and exact decision-making control.

## 2.4 How E.ON can close capability gaps (a consultant's practical approach)

An actual Capability Plan would encompass the above three components I have discussed above: hiring, up-skilling and partnerships.

1. Role specific upskilling: Grid engineers will be taught in relation to Digital Grid (sensors, digital twins, and data interpretation). The sales departments will be trained on how to make evidence-based choices. Making Leaders will be aware of Product Operating Models.

2. In teams of small specialists called Centers of Enablement (not Ivy Tower CoE) would design standards, coaching and reusable components before they would pressure business squads.

3. Talent strategy according to mission: The magnitude and aim of impact are the main distinguishing factors in case utilities and tech compete in digital talent. The idea of the modernization of the grids and the transition is noble, and it should be put into the form of practical tools and stimulating jobs.

4. Partner Ecosystem for Acceleration: Deploy partners rarely to develop the platform and harden the security and hold on to strategic data and domain knowledge internally.

CHAPTER THREE

# 3. Personalisation as a growth lever and enabler of innovation

## 3.1 Why personalisation matters in energy (beyond "marketing")

The importance of personalisation in energy (other than marketing) Energy personalization is required because it leads to a better retention, cheaper cost to serve and value pools like flexibility, electrification and distributed energy services by converting invisible usage into actionable intelligence. The EU policy on digitalization of the energy sector lays a lot of emphasis on the concept of data access and access to empower new products and empower their customers, that suggests that in the future, the market design will be personalized. Therefore, E.ON is eager to provide tailored advice and seamless service to provide electrification (EV charging, heat pumps, rooftop solar and storage) to offer comfort, control cost, reliability, decarbonization, which are all appealing to the notion of digitalization as one of the enabling factors on the foundation level.

## 3.2 What "good personalisation" looks like for E.ON

Personalisation should not be treated as a campaign, but as a skill. In effect it can be built in four layers:

**Layer 1 — Personalised energy insight (trust-first):**
Customers get personal information on the consumption trend, payment motivation and useful solutions. This is a less controversial form of personalization, which limits the number of inbound contacts and the churn on bill-shocks by telling the story of the customer instead of applying behavioral strategies. Digitally, the EU has been enabled to increase the level of control over cost and energy consumption.

**Layer 2 — Personalised tariffs and bundles (value + simplicity):**
Immediately perception has been acquired, E.ON can switch to the personalised offers: time-of-

use tariffs, EV packages or heat packages that will be adjusted to the usage patterns and limitations. The important design rule in this scenario is explainability: customers should know why a recommendation should be suitable to them. Otherwise, the personalisation would be a liability of trust.

**Layer 3 — Personalised flexibility participation (system value + customer value):**
The flexibility is found to be economically important because the grids get strained during electrification. The grid analysis performed by IEA points out that grids can become the constraint to clean energy transitions and more focus is given to the advantages of tools that reduce peaks or demand shift. The grid requirements in the case of E.ON can be converted to customer incentives i.e. Charge your EV at a lower price after 22: 00, we will automate it and share the savings. It is a direct association between customer experience and grid resilience.

**Layer 4 — Personalised service operations (proactive, not reactive):**
Personalisation should also be used to increase the perception of reliability. Examples: location based outage messaging and household based outage messaging, schedule appointments and receive messages about the status. This will enable the customer to work less and save brand loyalty when it is most needed.

### 3.3 Personalisation as a driver of innovation (how it creates new products)

Personalisation as an innovation driver In the form of an observed customer need, product hypothesis, test service, scaled offers, provides new cycles through which E.ON can resort to platform-based thinking. The case study of BCG Platiron demonstrates that E.ON desires to establish global digital selling platforms and a unified technological platform and establish an extensive array of automation both at the grid level and at the sales process. When this is done successfully then it will offer a platform through which the product offerings can be subjected to repeatable testing and scaling to various markets.Innovation pathways are particularly applicable along three areas:

1. Electrification concierge offering (EV + heat pump + PV + storage) : Customers are not interested in buying them separately. Their desires are end-to-end solution and minimum hand-offs. Personalisation identifies the right course of action and financing source of every household.

2. Partnerships with data (equipment manufacturers/installers/mobility platforms): Innovation in this case is based on the creation of open and interoperable APIs and a consent mechanism aligned with the EU priorities of forming an exchange data infrastructure.

3. Digital Grid Services: Commercializing the following capabilities: The ability to connect faster, accurate planning, and orchestrated flexibility. Although returns might be controlled by the regulatory agencies, an excellent performance can bring more confidence to the stakeholders of the business and ease of delivering investment.

## 3.4 Risks and limits: why personalisation should be constructed with an ethical approach

**Individualising Energy with Distrust:**

Personalisation of energy can easily move towards being perceived as invasive ("why do you know about my house, etc.) In order to prevent the same perception of intrusion there are two fundamentals to be followed:

- **Designing to be consent and transparent;** this involves seeking a clear and express consent of the consumer to each individual data piece that is gathered, the language used to explain the use of the data is plain and an easy way to opt-out of the data collection is provided.
- **Gathering just enough data to offer meaningful service;** when you gather excessive amounts of data, you widen your cyber and reputational risks (this will also create trust - see below).

The so-called trust first approach to personalising energy can be viewed as the ethical norm, yet, it is also a strategic option in the world where the regulations are becoming more common and the long term competitive edge of the companies is based on their capability to prove their legitimacy.

CHAPTER FOUR

# 4.Roadmap—opportunities, challenges, and delivery approach

## 4.1 A transformation roadmap that fits E.ON's reality

To have a viable roadmap there must be two realities which the roadmap must be founded on simultaneously.

1) E.ON has already started its digitalization process (adherence to industry requirements and cloud orientation on the strategy level).

2) There are still numerous impediments to utilities: technical, organizational, regulatory, economic and human capital based that will retard or halt the process of digitalization unless tackled as a complete system of processes.

As such, this roadmap is divided into three stages where stage one creates the groundwork, stage two speeds up the rate of implementation and stage three scales and entrenches.

## 4.2 Phase 1 — Foundations (0–12 months): make "platform + governance" real

**Purpose:** less fragmentation and develop a speed of delivery without control.

Key actions:

**The deployment of a Personalization Engine:** Implement a regulated recommendation engine on Tariffs/Bundles and Flexibility Offers according to consent laws on users.

**Phase 1 Accomplishment to the Platform Unification:** Explore a Universal Technology Platform in Markets Bearing similarities to E.ON that also claim they are on the same path of consolidated digital selling platforms.

**Enhance Cybersecurity of Critical Infrastructure:** Security-by-Design, OT Segmentation, Incident Playbooks, and Supplier Requirements to Security.

**Reset Operating Model (Thin But Real):** Design Cross-Functional Product Teams on Priority Journeys (i.e. "Grid Connection Lifecycle," Customer Onboarding of EV and Outage Communication). Success Criteria should be outcome-based (Cycle Time, Reliability and Customer Effort).

**Quick wins (to build credibility):**

Automate and Computerize a quantifiable part of the connection procedure (Status Visibility, Document Handling, Scheduling). Acknowledged as a Bottleneck Longer Than Once by the IEA; Making Connection Processes Faster Adds to Transition Pace.

### 4.3 Phase 2 - Speeding up Delivery (12- 24 Months) Scale What Works, Industrialize Value.

**Purpose:** Verb To Change Foundational Elements into Repeatable Delivery and Visible Performance Improvement.

Key actions:

**Scale Process Automation:** Process Mining + Automation to Large Scale Operations (Billing Inquiries, Move-In/Move-Out, Service Provisioning).

**Ensure Greater Digital grid Capabilities:** Correlate a higher level of observability and Predictive maintenance Where ROI and Reliability Impact are best; Incorporate Analytics into Decision Workflows, not dashboards. The Subsystem Deployment Is the Way to Go; It Should Not Be Individual Pilots but Adoption of End to end functionality.

**Roll Out Personalization Engine:** Develop a Governed Recommendation Engine of Tariffs/Bundles and Flexibility Offers on Consent Rules. Unite Platform Milestones: Seek Market-wide Technology Platforms Where Practical--In Line with E.ON Stated Direction and External Case Content on the Existence of a Unified Digital Sales Platform Path.

## 4.4 Phase 3 — Scale and institutionalise (24–36 months): make the advantage durable

**Goal:** Create a Lock in with Learning Loops, Interoperability and Positioning within the **Ecosystem.**Key actions:

- Ecosystem APIs + Partner Onboarding: Empower the Device Manufacturers, Installers, and Mobility Platforms to connect safely and supporting Innovation and Convenience to the Customer, in line with the EU ambitions over Interoperable Solutions and Data Sovereignty.

- Flexibility Orchestration Maturity: Increased Performance in Demand Response Programs through Automated Customer Programs (EV, Heating, Storage), with Unambiguous Value-Sharing. This Solves the Grid Constraint Issue and Differentiation of Customer Proposition of E.ON.

- Capability Flywheel: Institutionalize Data, Platforms and Products Roles Talent Pipelines, Internal Academies and Career Paths. Ensure Capabilities Do Not Remain in Central Teams, and move into Business Units.

## 4.5 Opportunities vs. challenges (and how to manage them)

**Opportunities:**

- Grid Reliability and Transition Speed: Capabilities of Digital Grids minimize the impact of congestion and enhance the planning and operations - Important Since Grids run the risk of becoming a bottleneck.

- Customer Differentiation: Personalization Makes Commodity Supply an Outcome-based Service and Lifetime Value.

- Cost-to-Serve Reduction: Automation Cuts Manual Labor in Processes with a High Volume, and the Manpower is used in Growth Areas.

**Challenges:**

- **Systems and integration debt:** they are typical of utilities; they are addressed by reference architecture, modularisation and proper sequencing.

- **Fragmentation of regulations across markets:** needs the adaptive regulation and local compliance overlay in the common platforms.

- **Skills shortage:** this issue will be dealt with through upskilling along with narrowed recruitment and partner strategy; the obstacle research highlights human and organisational elements as unrelenting limitations.

- **Cyber risk:** the more something is digitised, the wider it becomes the target of the attack; security should be a business facilitator, not an IT box to be ticked.

## 4.6 Governance and measurement (how E.ON ensures delivery)

A transformation of consultant grade needs to be measured tightly:

- North Star metrics connection lead time, outage restoration time, cost to serve, customer effort score, digital self service adoption, and flexibility participation rates.

- **Transformation cadence:** quarterly value reviews tied to outcomes; architecture/security guardrails with fast approvals for compliant teams.

- **Portfolio discipline:** abandon or re-design programs that fail to deliver any measurable results- preventing digital theatre.

# CONCLUDING REMARKS

The Digital Transformation advantages E.ON will receive will not be highly dependent on the new technology but rather the possibility to develop the proper cohesive capabilities, which will make E.ON transform digitalization into Reliability, Speed and Customer Value. The Grids face quite a significant risk of becoming the bottle neck of Clean Energy, hence the Strategic Imperatives are the digitalization of the Grid (Digital Grid Capability) and Process Acceleration. There should be four areas of priority to be taken together: Treat digitalization as the logic of operation of a more complex grid and electrified demand; Invest in Data, Platform Engineering, Cybersecurity, Product Operating Models and balance Safety with Speed; Use Personalization to shift to Outcome based Services, Built on Transparency and Consent; and Implement a Phased Roadmap to Organizational and Regulatory Barriers. The Strategy to Skills discipline enables E.ON to achieve faster connections and service, reduce friction in operations, increase loyalty and build resilience as technologies keep on evolving.
